Description

The CAT25512 is a EEPROM Serial 512−Kb SPI device internally organized as 64Kx8 bits. This features a 128−byte page write buffer and supports the Serial Peripheral Interface (SPI) protocol. The device is enabled through a Chip Select ($\overline{CS}$) input. In addition, the required bus signals are clock input (SCK), data input (SI) and data output (SO) lines. The $\overline{HOLD}$ input may be used to pause any serial communication with the CAT25512 device. The device features software and hardware write protection, including partial as well as full array protection.

On−Chip ECC (Error Correction Code) makes the device suitable for high reliability applications.

Features

- 20 MHz SPI Compatible
- 1.8 V to 5.5 V Supply Voltage Range
- SPI Modes (0,0) & (1,1)
- 128−byte Page Write Buffer
- Additional Identification Page with Permanent Write Protection
- Self−timed Write Cycle
- Hardware and Software Protection
- Block Write Protection
  − Protect $^1/_4$, $^1/_2$ or Entire EEPROM Array
- Low Power CMOS Technology
- 1,000,000 Program/Erase Cycles
- 100 Year Data Retention
- Industrial and Extended Temperature Range
- SOIC, TSSOP 8−lead, UDFN 8−pad
- This Device is Pb−Free, Halogen Free/BFR Free, and RoHS Compliant

(Top View)

PIN FUNCTION

Pin Name	Function
$\overline{CS}$	Chip Select
SO	Serial Data Output
$\overline{WP}$	Write Protect
V_{SS}	Ground
SI	Serial Data Input
SCK	Serial Clock
$\overline{HOLD}$	Hold Transmission Input
V_{CC}	Power Supply

ORDERING INFORMATION

See detailed ordering and shipping information in the package dimensions section on page 11 of this data sheet.

Table 1. ABSOLUTE MAXIMUM RATINGS

Parameters	Ratings	Units
Operating Temperature	−45 to +130	°C
Storage Temperature	−65 to +150	°C
Voltage on any Pin with Respect to Ground (Note 1)	−0.5 to +6.5	V

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. The DC input voltage on any pin should not be lower than −0.5 V or higher than V_{CC} + 0.5 V. During transitions, the voltage on any pin may undershoot to no less than −1.5 V or overshoot to no more than V_{CC} + 1.5 V, for periods of less than 20 ns.

Table 2. RELIABILITY CHARACTERISTICS (Note 2)

Symbol	Parameter	Max	Units
N_{END} (Note 3, 4)	Endurance	1,000,000	Program / Erase Cycles
T_{DR}	Data Retention	100	Years

2. These parameters are tested initially and after a design or process change that affects the parameter according to appropriate AEC−Q100 and JEDEC test methods.
3. Write Mode: groups of 4 bytes, 25°C.
4. The device uses ECC (Error Correction Code) logic with 6 ECC bits to correct one bit error in 4 data bytes. Therefore, when a single byte has to be written, 4 bytes (including the ECC bits) are re−programmed. It is recommended to write by multiple of 4 bytes in order to benefit from the maximum number of write cycles.

Table 3. D. C. OPERATING CHARACTERISTICS

(V_{CC} = 1.8 V to 5.5 V, T_A = −40°C to +85°C and V_{CC} = 2.5 V to 5.5 V, T_A = −40°C to +125°C, unless otherwise specified)

Symbol	Parameter	Test Conditions		Min	Max	Units
I_{CCR}	Supply Current (Read Mode)	Read, SO open / −40°C to +85°C	V_{CC} = 1.8 V, f_{SCK} = 5 MHz		1.2	mA

V_{IL2}	Input Low Voltage	V_{CC} < 2.5 V		−0.5	0.25V_{CC}	V
V_{IH2}	Input High Voltage	V_{CC} < 2.5 V		0.75V_{CC}	V_{CC} + 0.5	V
V_{OL1}	Output Low Voltage	V_{CC} ≥ 2.5 V, I_{OL} = 3.0 mA			0.4	V
V_{OH1}	Output High Voltage	V_{CC} ≥ 2.5 V, I_{OH} = −1.6 mA		V_{CC} − 0.8V		V
V_{OL2}	Output Low Voltage	V_{CC} < 2.5 V, I_{OL} = 150 μA			0.2	V
V_{OH2}	Output High Voltage	V_{CC} < 2.5 V, I_{OH} = −100 μA		V_{CC} − 0.2V		V

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

Status Register

The Status Register, as shown in Table 8, contains a number of status and control bits.

The $\overline{\text{RDY}}$ (Ready) bit indicates whether the device is busy with a write operation. This bit is automatically set to 1 during an internal write cycle, and reset to 0 when the device is ready to accept commands. For the host, this bit is read only.

The WEL (Write Enable Latch) bit is set/reset by the WREN/WRDI commands. When set to 1, the device is in a Write Enable state and when set to 0, the device is in a Write Disable state.

The BP0 and BP1 (Block Protect) bits determine which blocks are currently write protected. They are set by the user with the WRSR command and are non−volatile. The user is allowed to protect a quarter, one half or the entire memory, by setting these bits according to Table 9. The protected blocks then become read−only.

The WPEN (Write Protect Enable) bit acts as an enable for the $\overline{\text{WP}}$ pin. Hardware write protection is enabled when the $\overline{\text{WP}}$ pin is low and the WPEN bit is 1. This condition prevents writing to the status register and to the block protected sections of memory. While hardware write protection is active, only the non−block protected memory can be written. Hardware write protection is disabled when the $\overline{\text{WP}}$ pin is high or the WPEN bit is 0. The WPEN bit, $\overline{\text{WP}}$ pin and WEL bit combine to either permit or inhibit Write operations, as detailed in Table 10.

The IPL (Identification Page Latch) bit determines whether the additional Identification Page (IPL = 1) or main memory array (IPL = 0) can be accessed both for Read and Write operations. The IPL bit is set by the user with the WRSR command and is volatile. The IPL bit is automatically reset after read/write operations.

The LIP (Lock Identification Page) bit is set by the user with the WRSR command and is non−volatile. When set to 1, the Identification Page is permanently write protected (locked in Read−only mode).

Note: The IPL and LIP bits cannot be set to 1 using the same WRSR instruction. If the user attempts to set (“1”) both the IPL and LIP bit in the same time, these bits cannot be written and therefore they will remain unchanged.

WRITE OPERATIONS

The CAT25512 device powers up into a write disable state. The device contains a Write Enable Latch (WEL) which must be set before attempting to write to the memory array or to the status register. In addition, the address of the memory location(s) to be written must be outside the protected area, as defined by BP0 and BP1 bits from the status register.

Write Enable and Write Disable

The internal Write Enable Latch and the corresponding Status Register WEL bit are set by sending the WREN instruction to the CAT25512. Care must be taken to take the $\overline{CS}$ input high after the WREN instruction, as otherwise the Write Enable Latch will not be properly set. WREN timing is illustrated in Figure 3. The WREN instruction must be sent prior to any WRITE or WRSR instruction.

The internal write enable latch is reset by sending the WRDI instruction as shown in Figure 4. Disabling write operations by resetting the WEL bit, will protect the device against inadvertent writes.

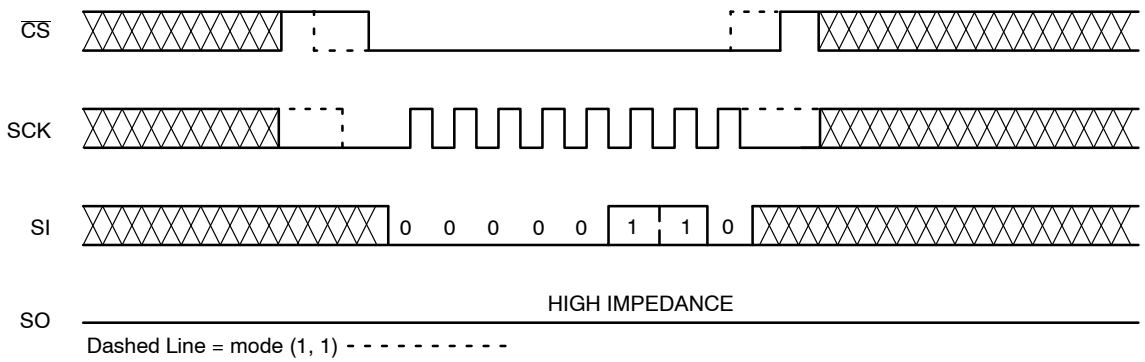

Figure 3. WREN Timing

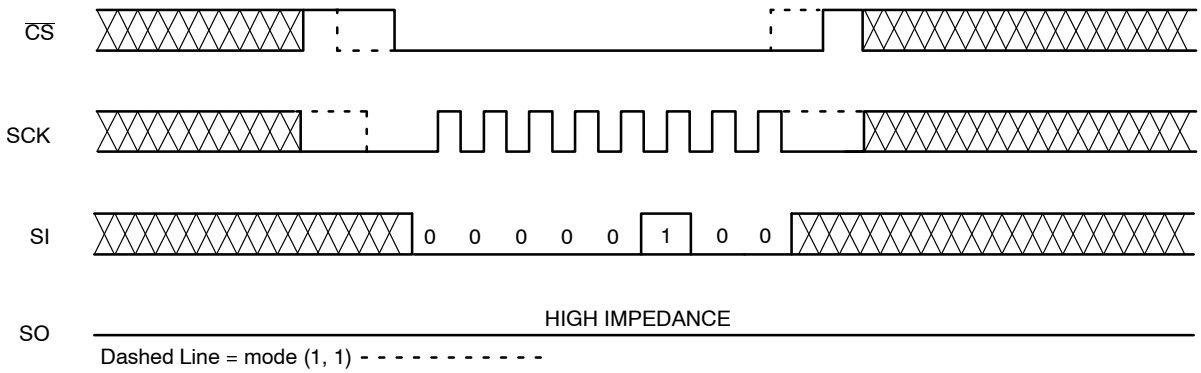

Figure 4. WRDI Timing

Byte Write

Once the WEL bit is set, the user may execute a write sequence, by sending a WRITE instruction, a 16−bit address and a data byte as shown in Figure 5. Internal programming will start after the low to high $\overline{CS}$ transition. During an internal write cycle, all commands, except for RDSR (Read Status Register) will be ignored. The $\overline{RDY}$ bit will indicate if the internal write cycle is in progress ($\overline{RDY}$ high), or the device is ready to accept commands ($\overline{RDY}$ low).

Page Write

After sending the first data byte to the CAT25512, the host may continue sending data, up to a total of 128 bytes, according to timing shown in Figure 6. After each data byte, the lower order address bits are automatically incremented, while the higher order address bits (page address) remain unchanged. If during this process the end of page is exceeded, then loading will "roll over" to the first byte in the page, thus possibly overwriting previously loaded data. Following completion of the write cycle, the CAT25512 is automatically returned to the write disable state.

Write Identification Page

The additional 128−byte Identification Page (IP) can be written with user data using the same Write commands sequence as used for Page Write to the main memory array (Figure 6). ***The IPL bit from the Status Register must be set (IPL = 1) using the WRSR instruction, before attempting to write to the IP.***

The address bits [A15:A7] are Don't Care and the [A6:A0] bits define the byte address within the Identification Page. In addition, the Byte Address must point to a location outside the protected area defined by the BP1, BP0 bits from the Status Register. When the full memory array is write protected (BP1, BP0 = 1,1), the write instruction to the IP is not accepted and not executed.

Also, the write to the IP is not accepted if the LIP bit from the Status Register is set to 1 (the page is locked in Read−only mode).

Table 11. BYTE ADDRESS

Device	Address Significant Bits	# Address Clock Pulses
Main Memory Array	A15 − A0	16
Identification Page	A6 − A0	16

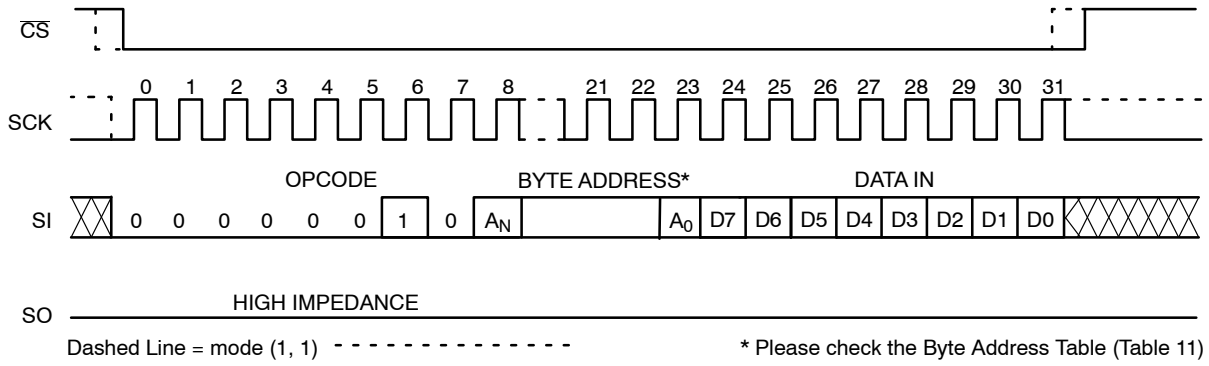

Figure 5. Byte WRITE Timing

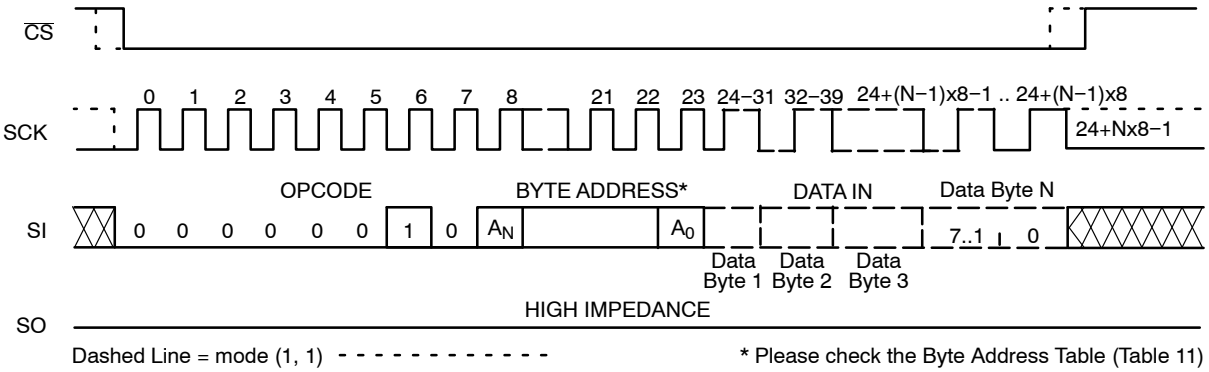

Figure 6. Page WRITE Timing

Write Status Register

The Status Register is written by sending a WRSR instruction according to timing shown in Figure 7. Only bits 2, 3, 4, 6 and 7 can be written using the WRSR command.

The internal programming for the SR bits will start after the low to high $\overline{CS}$ transition. The internal write cycle will last maximum 5 ms (t_{WC}).

It is recommended to avoid SR polling routine (through RDSR) while writing to the status register is in progress and insert a fixed delay of 5 ms before sending any other instruction to the CAT25512.

Write Protection

The Write Protect ($\overline{WP}$) pin can be used to protect the Block Protect bits BP0 and BP1 against being inadvertently altered. When $\overline{WP}$ is low and the WPEN bit is set to "1", write operations to the Status Register are inhibited. $\overline{WP}$ going low while $\overline{CS}$ is still low will interrupt a write to the status register. If the internal write cycle has already been initiated, $\overline{WP}$ going low will have no effect on any write operation to the Status Register. The $\overline{WP}$ pin function is blocked when the WPEN bit is set to "0". The $\overline{WP}$ input timing is shown in Figure 8.

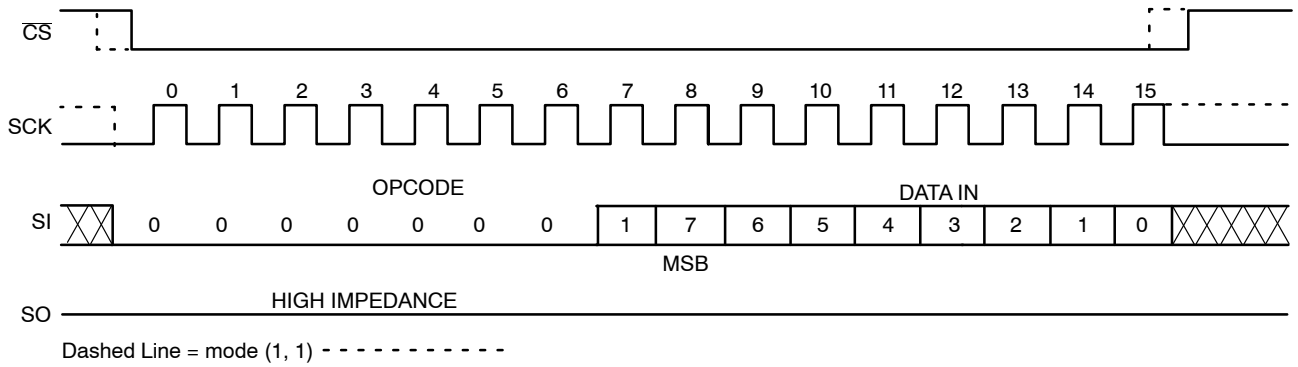

Figure 7. WRSR Timing

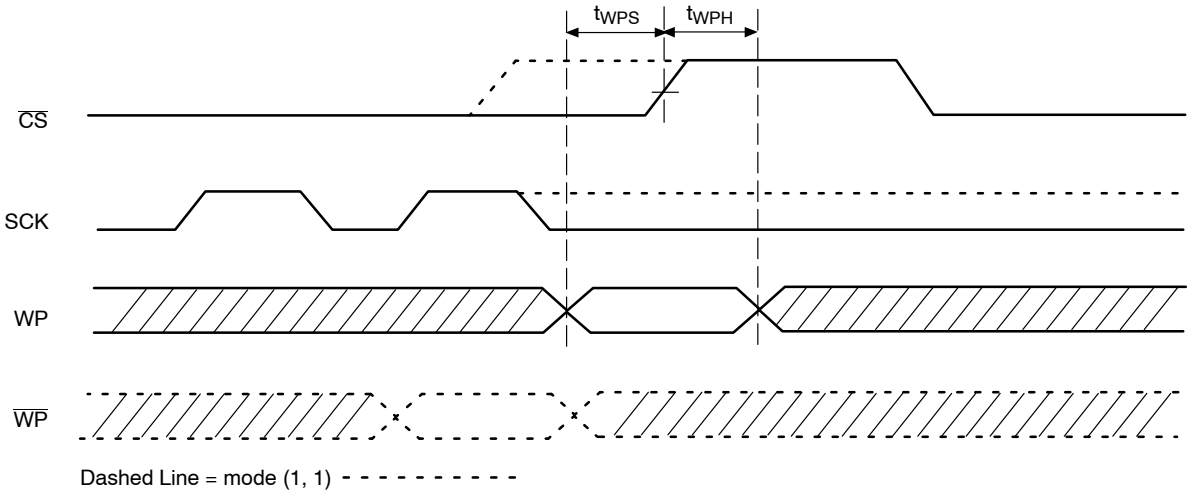

Figure 8. $\overline{WP}$ Timing

READ OPERATIONS

Read from Memory Array

To read from memory, the host sends a READ instruction followed by a 16−bit address.

After receiving the last address bit, the CAT25512 will respond by shifting out data on the SO pin (as shown in Figure 9). Sequentially stored data can be read out by simply continuing to run the clock. The internal address pointer is automatically incremented to the next higher address as data is shifted out. After reaching the highest memory address, the address counter “rolls over” to the lowest memory address, and the read cycle can be continued indefinitely. The read operation is terminated by taking $\overline{CS}$ high.

Read Identification Page

Reading the additional 128−byte Identification Page (IP) is achieved using the same Read command sequence as used for Read from main memory array (Figure 9). ***The IPL bit from the Status Register must be set (IPL = 1) before attempting to read from the IP.*** The [A6:A0] are the address significant bits that point to the data byte shifted out on the SO pin. If the CS continues to be held low, the internal address register defined by [A6:A0] bits is automatically incremented and the next data byte from the IP is shifted out. The byte address must not exceed the 128−byte page boundary.

Read Status Register

To read the status register, the host simply sends a RDSR command. After receiving the last bit of the command, the CAT25512 will shift out the contents of the status register on the SO pin (Figure 10). The status register may be read at any time, including during an internal write cycle.

While the internal write cycle is in progress, the RDSR command will output the full content of the status register. For easy detection of the internal write cycle completion, both during writing to the memory array and to the status register, we recommend sampling the RDY bit only through the polling routine. After detecting the RDY bit “0”, the next RDSR instruction will always output the expected content of the status register.

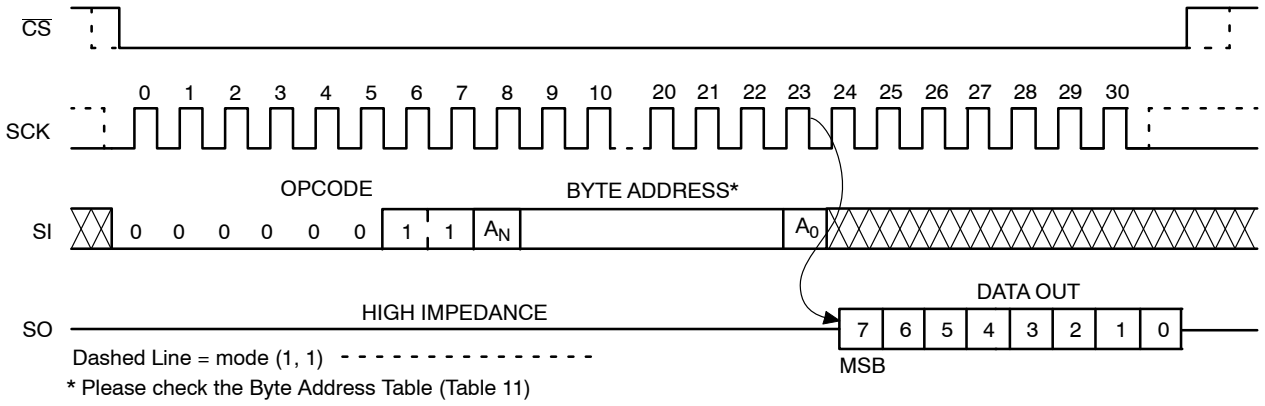

Figure 9. READ Timing

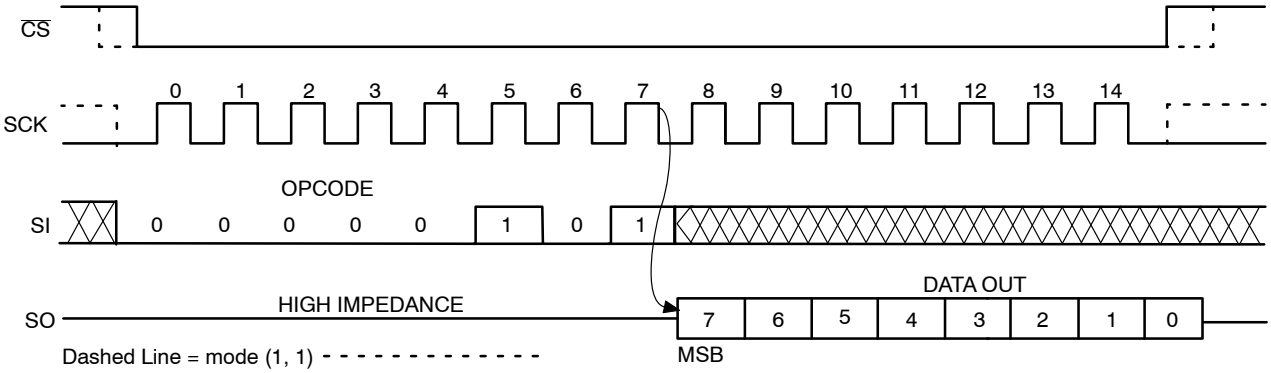

Figure 10. RDSR Timing

Hold Operation

The $\overline{\text{HOLD}}$ input can be used to pause communication between host and CAT25512. To pause, $\overline{\text{HOLD}}$ must be taken low while SCK is low (Figure 11). During the hold condition the device must remain selected ($\overline{\text{CS}}$ low). During the pause, the data output pin (SO) is tri−stated (high impedance) and SI transitions are ignored. To resume communication, $\overline{\text{HOLD}}$ must be taken high while SCK is low.

Design Considerations

The CAT25512 device incorporates Power−On Reset (POR) circuitry which protects the internal logic against powering up in the wrong state. The device will power up into Standby mode after V_{CC} exceeds the POR trigger level and will power down into Reset mode when V_{CC} drops below the POR trigger level. This bi−directional POR behavior protects the device against 'brown−out' failure following a temporary loss of power.

The CAT25512 device powers up in a write disable state and in a low power standby mode. A WREN instruction must be issued prior to any writes to the device.

After power up, the CS pin must be brought low to enter a ready state and receive an instruction. After a successful byte/page write or status register write, the device goes into a write disable mode. The CS input must be set high after the proper number of clock cycles to start the internal write cycle. Access to the memory array during an internal write cycle is ignored and programming is continued. Any invalid op−code will be ignored and the serial output pin (SO) will remain in the high impedance state.

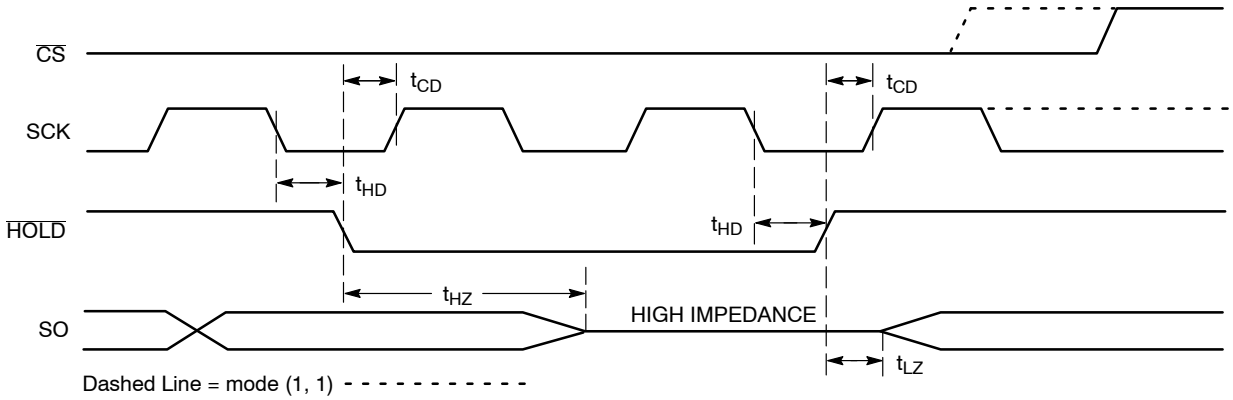

Figure 11. $\overline{\text{HOLD}}$ Timing
